

MoneyGraph Platform User Guide

1. Platform Overview

MoneyGraph is an AI-powered investment graph designed to track capital relationships between public and private entities. The platform sources its data from SEC filings, RSS feeds, and broader web searches to map out who is funding whom in the global market. To ensure high data integrity, every essential piece of information undergoes a human review step before it is formally integrated into the master graph.

2. The Force-Directed Graph

The platform features a dynamic, force-directed graph that visualises every tracked capital relationship. Nodes are colour-coded to distinguish between public companies, private companies, and "dark horse" entities. The physical size of a node scales based on its edge count, allowing users to instantly identify the most connected players in a network. Users can further refine this view using filters for category, country, role, and specific exchanges.

3. Node Profile Details

Selecting any node within the graph opens a comprehensive profile providing granular detail on that entity. These profiles include the organisation's sector, location, and founding information. For financial analysis, the system displays both confirmed and estimated investment totals. Additionally, public companies include a stock price chart, while all nodes list the specific news items that generated their connection edges.

4. The Master Data Table

For rapid scanning and data retrieval, the 'Nodes' section presents all tracked entities in a sortable table format. This view organises companies by ticker, type, sector, and country. It serves as the most efficient way to find specific entities or to analyse connectivity metrics, such as total edge count, across a broad list of organisations.

6. The Review Queue

The Review Queue acts as a critical human checkpoint between raw data extraction and confirmed graph inclusion. Newly discovered entities are held here, where administrators can approve them as new nodes, reject them, or link them to existing entries. The "Link" functionality is particularly vital for resolving fuzzy-matched candidates, such as subsidiaries or abbreviations, to prevent graph fragmentation.

7. System History

The 'Runs' dashboard provides a complete audit trail of the platform's background operations. This includes a history of every EDGAR filing sweep, RSS update, and web search run. Users can monitor the status and duration of each run, as well as the specific volume of nodes, edges, and candidates produced. The system also tracks the estimated cost per run for financial oversight.

Harvest batches

Re-resolve

Harvest polls OpenAI batch runs and writes results; it also runs automatically every 15 min. Re-resolve recovers edges from existing news whose companies just got approved; it also runs automatically after every EDGAR run.
